Summary

Software engineer with 4+ years of experience building backend services, event-driven systems, REST APIs and cloud-native platforms across tax configuration, supply-chain monitoring and recommendations. Designs reusable platform capabilities rather than one-off features: a shared telemetry library, an AST-based filtering framework, a signed-versioned agent registry and a layered database-intelligence service. Hands-on with Java, Go, Python, Node.js, AWS, Azure, Kafka, MongoDB, PostgreSQL, CDC, Kubernetes and observability, with strong API design, testing and CI/CD discipline and measurable gains in operational efficiency.

Technical Skills

Languages:	Java 17, Go (Golang), Python, TypeScript, JavaScript, SQL
Backend:	Spring Boot, Spring Cloud, FastAPI (async), Node.js, REST, OpenAPI 3.0, GraphQL, Microservices, Event-Driven Architecture, API Design, AST-based Query Engines
Distributed Systems:	Idempotent Event Handling, Multi-tenant Authorization, Caching, Schedulers (SKIP LOCKED), SSE Streaming, Fail-open Design
Cloud & Messaging:	AWS Lambda, ECS, EKS, EC2, S3, Step Functions, SQS, SNS, Kinesis, Kafka, Azure Key Vault
Data:	PostgreSQL, MongoDB, MySQL, DynamoDB, Redis, SQLAlchemy, Change Data Capture, Debezium
Observability:	OpenTelemetry, Datadog, Langfuse, Distributed Tracing, Metrics, Structured Logging, Trace Correlation, SLF4J MDC
DevOps & Testing:	Docker, Kubernetes, Helm, Terraform, Terragrunt, Pulumi, GitHub Actions, CircleCI, Maven BOM, JUnit, Mockito, Karate, pytest, Ruff
AI Platform:	LangGraph, MCP, RAG, Hybrid Retrieval, LLM Evaluation

Experience

Accenture Jan 2022 – Present

Application Development Senior Analyst

O-Series and AI CoE (Vertex GCC) – Java, Golang, Spring, Python, FastAPI

- Built an internal agent platform on async FastAPI and PostgreSQL: HMAC-signed, content-hashed immutable versioned registry with verify-on-read, policy-driven tool governance with an audited decision table, SKIP LOCKED schedule runner, SSE streaming, Postgres checkpointer and store with fail-open to memory, MCP registry with tool-risk scanning and approval lifecycle, hosted connectors, tenant budgets with a kill switch, and Terraform, Terragrunt and CI/CD for dev and prod.
- Designed a ∼24-endpoint REST API (runs, systems under test, datasets, experiments, suites; pagination, soft delete, ID validation, bearer-token auth) to remove direct database access from AI-evaluation clients; diagnosed the slug versus content-hash primary-key conflict behind run foreign-key failures and logged 25 design conflicts in an architecture and gap analysis.
- Built the event-driven AuthZ custom-roles sync (create and update via bulk upsert, delete via resolve-then-delete) with runtime environment-to-pod resolution replacing a hard-coded target; designed an immutable, caller-supplied Platform UID with a dedicated lookup API covering persistence, OpenAPI contract, cache, and uniqueness and immutability rules; designed a DB-first, AuthZ-fallback path for custom-role-only users; supported end-to-end defect triage (stale updates, 64-character name boundary).
- Owned DB-Agent (Python, FastAPI): layered architecture (entry points, orchestrator with uniform request tracing, engines, read-only providers) with enforced module boundaries, strategy, adapter, factory, facade and registry patterns, bearer auth, rate limiting, unified error envelope, P95 latency budget, LRU caching, a spec-first contract-parity test, a 17-tool MCP server, and monorepo analysis cut from 6+ GB and hours to 284 s at ∼250 MB via directory pruning, size caps and inverted-index linking.
- Developed REST V3 configuration APIs: translated requirements into OpenAPI contracts, implemented controller and service layers, mappings, validation, partition-aware authorization and audit logging, with JUnit and Karate coverage; delivered Taxability Driver create and Taxability Mapping create and get-by-ID with ID-based customer and vendor caching; resolved UUID versus internal-ID and natural-key consistency issues.
- Designed and implemented a reusable AST-based filtering framework (AND, OR, parentheses, equality, IN, contains, extensible to NOT) so V3 list and search endpoints share one testable pipeline instead of per-endpoint parsers; raised GraphQL versus REST trade-offs in design review and demoed it in sprint discussions.
- Built OpenTelemetry and Datadog observability: a shared Java telemetry library with a Maven BOM and publishing automation, migration of existing instrumentation, runtime trace-attribute enrichment, and customer-context enrichment of cloud logs through Spring-managed services and SLF4J MDC, behind a configuration switch with no measurable regression and no change for On-Prem and On-Demand; validated log, span and metric correlation in Datadog.

DISCO – Supply Chain Monitoring (Node.js, Golang, Java, AWS)

- Built event-driven services on AWS SAM (Node.js, TypeScript, Lambda, MongoDB, GraphQL APIs) and integrated applications to give other teams accurate observability; deployed and managed services on Lambda, EC2 and ECS.
- Contributed to a Java/MongoDB CDC service streaming real-time changes to AWS Kinesis; led the Java 17 upgrade and the Debezium migration to a newer stable version, improving compatibility, security and reliability.
- Built a Go Audit Connector on ECS that consumes Kafka audit messages, deserializes Protocol Buffers to JSON and publishes to SNS for downstream consumers.
- Designed a Tags API from scratch (global, group, individual tagging) for launches and hypercare; moved from Lambda to ECS with an SQS consumer for reliable polling, helping identify 100% of problematic events in real time.

- Automated data archiving with AWS Step Functions to S3, removing ∼1.8M records from MongoDB collections and saving ∼20 hours of manual work every three months; built a reusable backfilling API replacing manual correction scripts, saving ∼20 hours per backfill.
- Redesigned the Go, HTMX and Tailwind monitoring UI to cut unnecessary API calls; migrated session management from icza/session to alexedwards/scs, fixing security concerns and supporting SAML 2.0 and OAuth 2.0.
- Developed a conversational offering-analysis assistant (Python, AWS Bedrock, LangChain, RAG) that explains status and blockers and recommends fixes; reduced support investigation time by ∼40%.

RECS – OTT Recommendations Platform (Java, Golang, AWS)

- Built Top 10, Recommended for You, YAML-based configuration, data pinning and hero-banner features using Amazon Personalize and an in-house ML platform; features increased customer retention by ∼30 minutes.
- Led the migration from ECS to Kubernetes on EKS and from CircleCI to GitHub Actions with Pulumi infrastructure as code; owned the full SDLC including bug fixing, unit testing and CI/CD production deployments.

Projects

Quick-Comers Observability POC – Java, Spring Boot, OpenTelemetry GitHub

- Made any service traceable end to end by building a reusable observability-core module (trace-context holder, servlet filter, interceptor, metrics service) that propagates trace IDs across order, inventory and payment flows into logs, exposes Prometheus metrics and forwards traces through an OpenTelemetry Collector; runs locally with one Docker Compose command.

Agentic Notification – Go, Java, React, PostgreSQL, Redis, NATS GitHub

- Designed a four-layer attention-orchestration platform (deterministic policy, AI attention intelligence, provider-agnostic delivery, feedback) where critical events bypass AI entirely and only low-risk events are classified; runs locally via Docker Compose.

Certifications

Anthropic: Claude Certified Architect – Foundations
Google Cloud: Agent Development Kit (ADK) and Gemini Enterprise
Accenture: Reinvention with Agentic AI

Education

Indian Institute of Technology Bhubaneswar 2021
Bachelor of Technology, Mechanical Engineering
